Portfolio Optimization

Risk Parity Portfolios

Daniel P. Palomar (2025). *Portfolio Optimization: Theory and Application.*
Cambridge University Press.

portfoliooptimizationbook.com

Latest update: 2025-10-29

Outline

Executive Summary

- Markowitz mean-variance portfolio optimizes return-risk trade-off using variance or volatility as a proxy for risk.
- However, quantifying the portfolio risk with a single number has inherent limitations.
- A more refined approach is to employ a **risk profile** that quantifies each asset's risk contribution to the portfolio.
- For this purpose, these slides explore the so-called **risk parity portfolios** (Palomar 2025, chap. 11).

Outline

Introduction

Markowitz's Mean-Variance Portfolio Optimization

$$\begin{array}{ll} \underset{\boldsymbol{w}}{\text{maximize}} & \boldsymbol{w}^\mathsf{T}\boldsymbol{\mu} - \frac{\lambda}{2}\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w} \\ \text{subject to} & \boldsymbol{w} \in \mathcal{W} \end{array}$$

where λ is a risk-aversion hyper-parameter and $\mathcal{W}$ is the constraint set, e.g., $\mathcal{W} = \{\boldsymbol{w} \mid \mathbf{1}^\mathsf{T}\boldsymbol{w} = 1, \boldsymbol{w} \geq \mathbf{0}\}$.

Limitations of Variance as Risk Measure

- Variance $\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}$ may not yield best out-of-sample performance.
- Alternative risk measures are considered for improvement.

Risk Profile Characterization

- Beyond a single risk number, assess risk contribution of each asset.
- Enables control over portfolio risk diversification.

Risk Parity Portfolio

- From simple forms with closed solutions to complex nonconvex formulations.
- Wide range of numerical algorithms available for implementation.

Outline

From Dollar to Risk Diversification

Risk Parity Investment Approach

- Focuses on equalizing risk contribution from each asset.
- Shifts from dollar allocation to risk allocation.

Concept of Risk Diversification

- Aims for assets to contribute equally to overall portfolio risk.
- Enhances out-of-sample risk control and market downturn resistance.

Historical Context

- Traditional allocations like 60/40 stock/bond portfolios dominated by equity risk.
- Risk parity emerged to address risk concentration issues.

Development and Popularity

- "All Weather" fund by Bridgewater Associates in 1996 initiated the practical application.
- Term "risk parity" coined by Edward Qian in 2005 (Qian 2005).
- Gained popularity post-2008 financial crisis.

From Dollar to Risk Diversification

Skepticism and Debate

- Some managers question its effectiveness across all market conditions.

Academic and Practitioner Interest

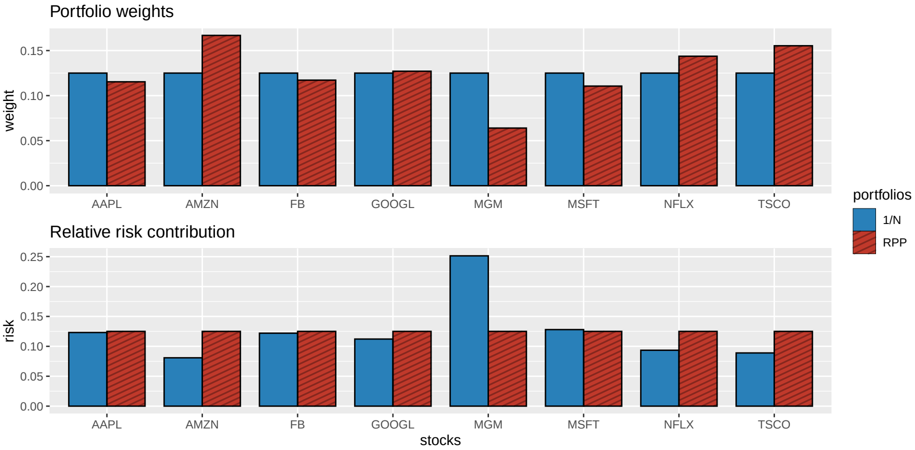
- Significant attention and numerous publications.
- Textbooks for both practical (Qian 2016) and mathematical (Roncalli 2013) perspectives.

Illustration of Diversification

- $1/N$ portfolio obtains capital allocation diversification, not risk diversification.
- Risk parity portfolio aims for balanced risk contribution across assets.

From Dollar to Risk Diversification

Portfolio allocation and risk allocation for the $1/N$ portfolio and risk parity portfolio:



Outline

Risk Contributions

Risk Contribution in Risk Parity Portfolio

- Portfolio risk as sum of individual asset risk contributions:

$$\text{portfolio risk} = \sum_{i=1}^{N} \mathrm{RC}_i,$$

where RC_i is the risk contribution of the ith asset.

Alternative Risk Measures

- Volatility, value-at-risk (VaR), conditional VaR (CVaR) are common risk measures.
- For detailed discussion, see (Palomar 2025, chap. 10).

Euler's Homogenous Function Theorem

- For positively homogeneous functions of degree one:

$$f(\boldsymbol{w}) = \sum_{i=1}^{N} w_i \frac{\partial f}{\partial w_i}.$$

Applies to volatility, VaR, CVaR, but not variance.

Risk Contributions

Risk Contribution Definitions

- Risk Contribution (RC):

$$\mathrm{RC}_i = w_i \frac{\partial f(\boldsymbol{w})}{\partial w_i}$$

- Marginal Risk Contribution (MRC):

$$\mathrm{MRC}_i = \frac{\partial f(\boldsymbol{w})}{\partial w_i}$$

- Relative Risk Contribution (RRC):

$$\mathrm{RRC}_i = \frac{\mathrm{RC}_i}{f(\boldsymbol{w})},$$

with $\sum_{i=1}^{N} \mathrm{RRC}_i = 1$.

Volatility Risk Contributions

Volatility:

$$\sigma(\boldsymbol{w}) = \sqrt{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}}$$

with partial derivatives:

$$\frac{\partial \sigma}{\partial w_i} = \frac{(\boldsymbol{\Sigma}\boldsymbol{w})_i}{\sqrt{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}}}.$$

Risk Contribution

- Risk contribution:

$$\mathrm{RC}_i = \frac{w_i(\boldsymbol{\Sigma}\boldsymbol{w})_i}{\sqrt{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}}}$$

- Relative risk contribution:

$$\mathrm{RRC}_i = \frac{w_i(\boldsymbol{\Sigma}\boldsymbol{w})_i}{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}}$$

Portfolio Volatility Decomposition:

$$\sigma(\boldsymbol{w}) = \sum_{i=1}^{N} w_i \frac{\partial \sigma}{\partial w_i} = \sum_{i=1}^{N} \frac{w_i(\boldsymbol{\Sigma}\boldsymbol{w})_i}{\sqrt{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}}}$$

CVaR Risk Contributions

CVaR:

$$\mathrm{CVaR}_\alpha(\boldsymbol{w}) = \mathbb{E}\left[-\boldsymbol{w}^\mathsf{T}\boldsymbol{r} \mid -\boldsymbol{w}^\mathsf{T}\boldsymbol{r} \geq \mathrm{VaR}_\alpha(\boldsymbol{w})\right]$$

with partial derivatives:

$$\frac{\partial \mathrm{CVaR}_\alpha(\boldsymbol{w})}{\partial w_i} = \mathbb{E}\left[-r_i \mid -\boldsymbol{w}^\mathsf{T}\boldsymbol{r} \geq \mathrm{VaR}_\alpha(\boldsymbol{w})\right].$$

Risk Contribution:

$$\mathrm{RC}_i = \mathbb{E}\left[-w_i r_i \mid -\boldsymbol{w}^\mathsf{T}\boldsymbol{r} \geq \mathrm{VaR}_\alpha(\boldsymbol{w})\right]$$

Portfolio CVaR Decomposition:

$$\mathrm{CVaR}_\alpha(\boldsymbol{w}) = \sum_{i=1}^{N} \mathbb{E}\left[-w_i r_i \mid -\boldsymbol{w}^\mathsf{T}\boldsymbol{r} \geq \mathrm{VaR}_\alpha(\boldsymbol{w})\right].$$

Outline

Problem Formulation

Risk Parity Portfolio (RPP) or Equal Risk Portfolio (ERP)

- Requires equal risk contributions from all assets:

$$\mathrm{RRC}_i = \frac{w_i(\boldsymbol{\Sigma}\boldsymbol{w})_i}{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}} = \frac{1}{N}, \qquad i = 1, \dots, N.$$

- Contrasts with the $1/N$ equally weighted portfolio (EWP) that equalizes dollar allocation.

Optimality Under Certain Conditions

- If assets have similar Sharpe ratios and correlations, RPP can align with Markowitz's mean-variance optimization.
- RPP is unique and falls between minimum variance and equally weighted portfolios.

Risk Budgeting Portfolio (RBP)

- Allows for a specified risk profile allocation:

$$\mathrm{RRC}_i = \frac{w_i(\boldsymbol{\Sigma}\boldsymbol{w})_i}{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}} = b_i, \qquad i = 1, \dots, N,$$

where $\boldsymbol{b} = (b_1, \dots, b_N)$ represents the desired risk profile, normalized to sum to 1.

Problem Formulation

Formulation of RBP

Find $\boldsymbol{w} \geq \mathbf{0}$, with $\mathbf{1}^\mathsf{T}\boldsymbol{w} = 1$, that satisfies:

$$w_i(\boldsymbol{\Sigma}\boldsymbol{w})_i = b_i\, \boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}, \qquad i = 1, \ldots, N.$$

This is a feasibility problem with constraints but no explicit objective.

Approaches to Solving RBP

- Naive diagonal formulation.
- Vanilla convex formulation.
- General nonconvex formulation.

Practical Implementation

- R package `riskParityPortfolio`.
- Python package `riskparityportfolio`.

Formulation with Shorting

Typical RPP Constraints

- No shorting allowed: $\boldsymbol{w} \geq \boldsymbol{0}$.
- Shorting introduces complexity in resolution methods.

Shorting Pattern Known a Priori

- If shorting pattern is predefined, problem simplification is possible.
- $\boldsymbol{s} = (s_1, \ldots, s_N)$ indicates long ($s_i = 1$) or short ($s_i = -1$) positions.

Portfolio Relation with Shorting Pattern

- Actual portfolio $\boldsymbol{w}$ related to a virtual no-shorting portfolio $\tilde{\boldsymbol{w}} \geq \boldsymbol{0}$:

$$\boldsymbol{w} = \boldsymbol{s} \odot \tilde{\boldsymbol{w}}$$

- Risk remains equivalent:

$$\boldsymbol{w}^\mathsf{T} \boldsymbol{\Sigma} \boldsymbol{w} = \tilde{\boldsymbol{w}}^\mathsf{T} \tilde{\boldsymbol{\Sigma}} \tilde{\boldsymbol{w}},$$

  where $\tilde{\boldsymbol{\Sigma}} = \text{Diag}(\boldsymbol{s}) \boldsymbol{\Sigma} \text{Diag}(\boldsymbol{s})$.
- Risk budgeting equations for virtual portfolio $\tilde{\boldsymbol{w}}$:

$$\tilde{w}_i (\tilde{\boldsymbol{\Sigma}} \tilde{\boldsymbol{w}})_i = b_i \, \tilde{\boldsymbol{w}}^\mathsf{T} \tilde{\boldsymbol{\Sigma}} \tilde{\boldsymbol{w}}, \qquad i = 1, \ldots, N.$$

Formulation with Group Risk Parity

Concept of Group Risk Parity

- Risk contributions of assets within the same group (e.g., industry or sector) are considered collectively.

Group Definition

- K groups, $\mathcal{G}_1, \dots, \mathcal{G}_K$, partition the N assets.
- Each group $\mathcal{G}_k$ contains assets that are treated as a single entity in terms of risk.

Group Risk Contribution

- Risk contribution from the kth group:

$$\mathrm{RC}_{\mathcal{G}_k} = \sum_{i \in \mathcal{G}_k} w_i \frac{\partial \sigma}{\partial w_i} = \sum_{i \in \mathcal{G}_k} \frac{w_i (\boldsymbol{\Sigma} \boldsymbol{w})_i}{\sqrt{\boldsymbol{w}^\mathsf{T} \boldsymbol{\Sigma} \boldsymbol{w}}}$$

Risk Budgeting for Groups

- Risk budgeting equations for groups:

$$\sum_{i \in \mathcal{G}_k} w_i (\boldsymbol{\Sigma} \boldsymbol{w})_i = b_k \, \boldsymbol{w}^\mathsf{T} \boldsymbol{\Sigma} \boldsymbol{w}, \qquad k = 1, \dots, K,$$

where b_k represents the risk budget for group k.

Formulation with Risk Factors

Factor Model for Returns

$$\boldsymbol{r}_t = \boldsymbol{\alpha} + \boldsymbol{B}\boldsymbol{f}_t + \boldsymbol{\epsilon}_t,$$

where $\boldsymbol{f}_t$ are the K factors (with $K \ll N$), $\boldsymbol{\alpha}$ is the "alpha", $\boldsymbol{B}$ is the matrix of "betas" for different factors, and $\boldsymbol{\epsilon}_t$ is the residual.

Risk Contribution from Factors

- Defined for the kth factor as:

$$\mathrm{RC}_k = \frac{(\boldsymbol{B}^\mathsf{T}\boldsymbol{w})_k(\boldsymbol{B}^\dagger\boldsymbol{\Sigma}\boldsymbol{w})_k}{\sqrt{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}}},$$

  where $\boldsymbol{B}^\dagger$ is the Moore-Penrose pseudo-inverse of $\boldsymbol{B}$.

Risk Budgeting in Factor Model

- Risk budgeting equations for factors:

$$(\boldsymbol{B}^\mathsf{T}\boldsymbol{w})_k(\boldsymbol{B}^\dagger\boldsymbol{\Sigma}\boldsymbol{w})_k = b_k\, \boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}, \qquad k = 1, \dots, K.$$

  where b_k is the risk budget for the kth factor.

Outline

Naive Diagonal Formulation

Risk Budgeting Equations with Diagonal Covariance

- For diagonal covariance matrix $\boldsymbol{\Sigma} = \mathrm{Diag}(\boldsymbol{\sigma}^2)$:

$$w_i^2 \sigma_i^2 = b_i \sum_{j=1}^{N} w_j^2 \sigma_j^2, \qquad i = 1, \ldots, N$$

- Simplifies to:

$$w_i = \frac{\sqrt{b_i}}{\sigma_i} \sqrt{\sum_{j=1}^{N} w_j^2 \sigma_j^2}, \qquad i = 1, \ldots, N.$$

Inverse Volatility Portfolio (IVolP)

- Portfolio weights inversely proportional to asset volatilities.
- Lower weights to high-volatility assets, higher weights to low-volatility assets.
- Results in equal volatility contribution from each asset for $b_i = 1/N$.

Naive Diagonal Formulation

General Nondiagonal Covariance Matrix

- No closed-form solution available; optimization required.
- Diagonal solution serves as a "naive" approach.

Portfolio Allocation and Risk Contribution

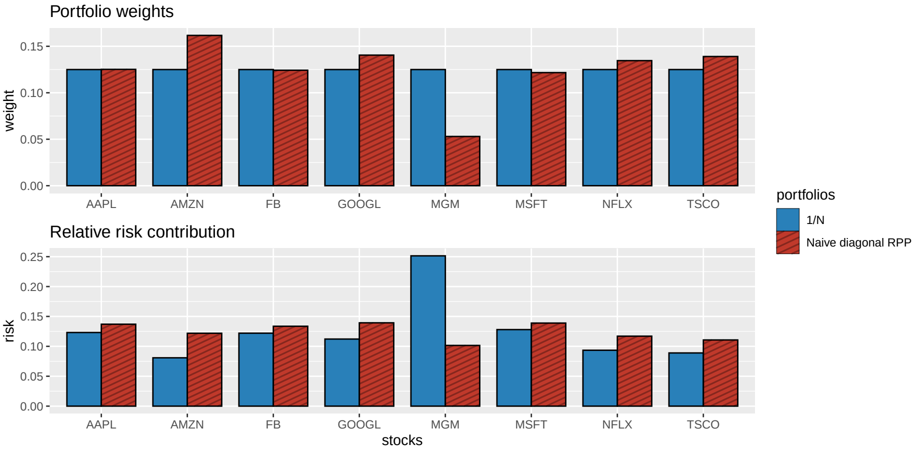
- The $1/N$ portfolio allocates capital equally across assets.
- However, it results in unequal risk contributions.

Naive Risk Parity Portfolio

- Achieves a more balanced risk contribution among assets.
- Not perfectly equalized due to ignoring off-diagonal covariance matrix elements.

Example: Naive RPP vs. $1/N$ Portfolio

Portfolio allocation and risk contribution of the $1/N$ portfolio and naive RPP:



Outline

Vanilla Formulation

Risk Budgeting Equations:

$$w_i \left(\boldsymbol{\Sigma} \boldsymbol{w}\right)_i = b_i \, \boldsymbol{w}^\mathsf{T} \boldsymbol{\Sigma} \boldsymbol{w}, \qquad i = 1, \ldots, N$$

with constraints $\mathbf{1}^\mathsf{T} \boldsymbol{w} = 1$ and $\boldsymbol{w} \geq \mathbf{0}$.

Change of Variable

- Define $\boldsymbol{x} = \boldsymbol{w} / \sqrt{\boldsymbol{w}^\mathsf{T} \boldsymbol{\Sigma} \boldsymbol{w}}$, then rewrite equations as:

$$x_i \left(\boldsymbol{\Sigma} \boldsymbol{x}\right)_i = b_i$$

- Vector form:

$$\boldsymbol{\Sigma} \boldsymbol{x} = \boldsymbol{b} / \boldsymbol{x}$$

- Portfolio recovery by normalizing $\boldsymbol{x}$:

$$\boldsymbol{w} = \boldsymbol{x} / (\mathbf{1}^\mathsf{T} \boldsymbol{x}).$$

Vanilla Formulation

Correlation Matrix Reformulation

- Rewrite in terms of correlation matrix $\boldsymbol{C}$:

$$\boldsymbol{C}\tilde{\boldsymbol{x}} = \boldsymbol{b}/\tilde{\boldsymbol{x}},$$

where $\boldsymbol{C} = \boldsymbol{D}^{-1/2}\Sigma\boldsymbol{D}^{-1/2}$ with $\boldsymbol{D} = \mathrm{Diag}(\boldsymbol{\sigma}^2)$, and $\boldsymbol{x} = \tilde{\boldsymbol{x}}/\boldsymbol{\sigma}$.

Numerical Benefits

- Normalizing returns with respect to asset volatilities can improve numerical stability.

Direct Resolution via Root Finding

Nonlinear Equations System

- System defined by $\boldsymbol{\Sigma}\boldsymbol{x} = \boldsymbol{b}/\boldsymbol{x}$.
- Interpreted as finding roots of $F(\boldsymbol{x}) = \boldsymbol{\Sigma}\boldsymbol{x} - \boldsymbol{b}/\boldsymbol{x}$.
- Goal: solve $F(\boldsymbol{x}) = \mathbf{0}$.

Root Finding in Practice

- Utilize general-purpose nonlinear multivariate root finders.
- Available in most programming languages.

Root-Finding with Budget Constraint

- Include budget constraint $\mathbf{1}^\mathsf{T}\boldsymbol{w} = 1$ in function:

$$F(\boldsymbol{w}, \lambda) = \begin{bmatrix} \boldsymbol{\Sigma}\boldsymbol{w} - \lambda\boldsymbol{b}/\boldsymbol{w} \\ \mathbf{1}^\mathsf{T}\boldsymbol{w} - 1 \end{bmatrix}.$$

Programming Tools

- R: use `multiroot()` from package `rootSolve` for multivariate root finding.
- Matlab: use `fsolve()` for solving systems of nonlinear equations.

Convex Optimization for Risk Budgeting

- Risk budgeting equations can be solved through convex optimization, revealing hidden convexity.

Spinu's Convex Formulation (Spinu 2013)

$$\underset{\boldsymbol{x}\geq\mathbf{0}}{\text{minimize}} \quad \frac{1}{2}\boldsymbol{x}^{\mathsf{T}}\boldsymbol{\Sigma}\boldsymbol{x} - \boldsymbol{b}^{\mathsf{T}}\log(\boldsymbol{x})$$

Equivalence to Risk Budgeting

- Gradient set to zero matches risk budgeting equation:

$$\boldsymbol{\Sigma}\boldsymbol{x} = \boldsymbol{b}/\boldsymbol{x}.$$

Convex Reformulations

Roncalli's Convex Formulation (Roncalli 2013)

$$\underset{\boldsymbol{x}\geq\mathbf{0}}{\text{minimize}} \quad \sqrt{\boldsymbol{x}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x}} - \boldsymbol{b}^\mathsf{T}\log(\boldsymbol{x})$$

- Gradient zero leads to a form similar to risk budgeting equation after renormalization.

Maillard, Roncalli, and Teiletche's Convex Formulation (Maillard, Roncalli, and Teiletche 2010)

$$\underset{\boldsymbol{x}\geq\mathbf{0}}{\text{minimize}} \quad \sqrt{\boldsymbol{x}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x}}, \quad \text{subject to} \quad \boldsymbol{b}^\mathsf{T}\log(\boldsymbol{x}) \geq c$$

- Minimizes volatility with a diversification constraint.

Convex Reformulations

Kaya and Lee's Convex Formulation (Kaya and Lee 2012)

$$\underset{\boldsymbol{x}\geq\boldsymbol{0}}{\text{maximize}} \quad \boldsymbol{b}^{\mathsf{T}}\log(\boldsymbol{x}), \quad \text{subject to} \quad \sqrt{\boldsymbol{x}^{\mathsf{T}}\boldsymbol{\Sigma}\boldsymbol{x}} \leq \sigma_0$$

- Gradient of Lagrangian matches risk budgeting equation after renormalization.

Solving Convex Formulations

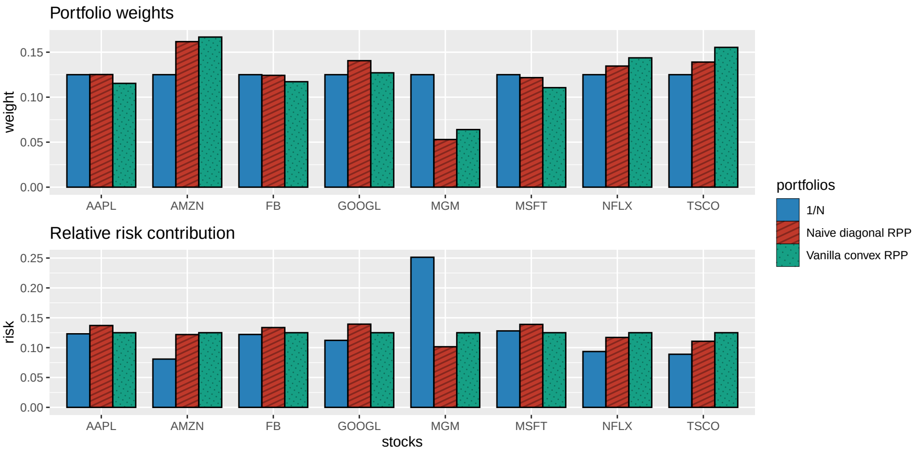
- General-purpose solvers can be used, available in programming languages like R (`optim()`) and Matlab (`fmincon()`).
- Tailored algorithms can offer simple and efficient solutions.

Key Insight

- These convex formulations provide different perspectives on achieving risk parity through optimization, each with its unique advantages and interpretations.

Example

Portfolio allocation and risk contribution of the vanilla convex RPP compared to benchmarks:



Vanilla Convex Formulations: Algorithms

Iterative Algorithms

- Develop practical algorithms for Spinu's and Roncalli's formulations.
- Generate a sequence of iterates $\boldsymbol{x}^0, \boldsymbol{x}^1, \boldsymbol{x}^2, \ldots$
- Important to have a good initial point $\boldsymbol{x}^0$ that attempts to approximate the solution to the nonlinear equations $\boldsymbol{\Sigma x} = \boldsymbol{b}/\boldsymbol{x}$.

Initial Point Options

Crucial for the convergence and efficiency of the algorithms.

- Naive diagonal solution:
$$\boldsymbol{x}^0 = \sqrt{\boldsymbol{b}}/\boldsymbol{\sigma}$$
- Diagonal row-sum heuristic:
$$\boldsymbol{x}^0 = \sqrt{\boldsymbol{b}}/\sqrt{\boldsymbol{\Sigma 1}}$$

Vanilla Convex Formulations: Newton's Method

Newton's Method Iteration

$$\boldsymbol{x}^{k+1} = \boldsymbol{x}^{k} - \mathsf{H}f(\boldsymbol{x}^{k})^{-1}\nabla f(\boldsymbol{x}^{k})$$

Gradient and Hessian for Spinu's Formulation

- For $f(\boldsymbol{x}) = \frac{1}{2}\boldsymbol{x}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x} - \boldsymbol{b}^\mathsf{T}\log(\boldsymbol{x})$:

$$\begin{aligned}\nabla f(\boldsymbol{x}) &= \boldsymbol{\Sigma}\boldsymbol{x} - \boldsymbol{b}/\boldsymbol{x}\\ \mathsf{H}f(\boldsymbol{x}) &= \boldsymbol{\Sigma} + \mathsf{Diag}(\boldsymbol{b}/\boldsymbol{x}^2).\end{aligned}$$

Application to RPP

- Newton's method can be applied to solve the risk parity portfolio optimization problem.
- The method uses the gradient and Hessian of the objective function to iteratively improve the solution.

Reference for Newton's Method

- Detailed study of Newton's method for risk parity portfolio in (Spinu 2013).
- For a general overview of gradient methods, see (Palomar 2025, Appendix B).

Vanilla Convex Formulations: Cyclical Coordinate Descent Algorithm

Algorithm Overview

- Minimize function $f(\boldsymbol{x})$ cyclically for each element x_i (not parallel update).
- Other elements of $\boldsymbol{x} = (x_1, \ldots, x_N)$ are held fixed during minimization.
- Known as block coordinate descent (BCD) (Palomar 2025, Appendix B).

Elementwise Minimization for Spinu's Formulation

$$\underset{x_i \geq 0}{\text{minimize}} \quad \frac{1}{2} x_i^2 \boldsymbol{\Sigma}_{ii} + x_i (\boldsymbol{x}_{-i}^{\mathsf{T}} \boldsymbol{\Sigma}_{-i,i}) - b_i \log x_i$$

where $\boldsymbol{x}_{-i}$ is the variable $\boldsymbol{x}$ without ith element, and $\boldsymbol{\Sigma}_{-i,i}$ is the ith column of $\boldsymbol{\Sigma}$ without ith element.

Closed-Form Solution

- Solve second order equation for x_i:

$$\boldsymbol{\Sigma}_{ii} x_i^2 + (\boldsymbol{x}_{-i}^{\mathsf{T}} \boldsymbol{\Sigma}_{-i,i}) x_i - b_i = 0,$$

- Positive solution:

$$x_i = \frac{-\boldsymbol{x}_{-i}^{\mathsf{T}} \boldsymbol{\Sigma}_{-i,i} + \sqrt{(\boldsymbol{x}_{-i}^{\mathsf{T}} \boldsymbol{\Sigma}_{-i,i})^2 + 4 \boldsymbol{\Sigma}_{ii} b_i}}{2 \boldsymbol{\Sigma}_{ii}}.$$

Vanilla Convex Formulations: Parallel Update via MM*

Majorization-Minimization (MM) Framework Overview (Sun, Babu, and Palomar 2017) (Palomar 2025, Appendix B)

- Solves optimization problems by iteratively solving simpler surrogate problems.
- Surrogate problems are designed to majorize (upper-bound) the objective function.

Decoupling Elements with MM

- The term $\boldsymbol{x}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x}$ couples all elements of $\boldsymbol{x}$, complicating parallel updates.
- MM framework allows for decoupling by using a particular majorizer for $\boldsymbol{x}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x}$.

Majorizer for $\boldsymbol{x}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x}$

$$\frac{1}{2}\boldsymbol{x}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x} \leq \frac{1}{2}(\boldsymbol{x}^k)^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x}^k + (\boldsymbol{\Sigma}\boldsymbol{x}^k)^\mathsf{T}(\boldsymbol{x}-\boldsymbol{x}^k) + \frac{\lambda_{\max}}{2}(\boldsymbol{x}-\boldsymbol{x}^k)^\mathsf{T}(\boldsymbol{x}-\boldsymbol{x}^k),$$

where $\lambda_{\max}$ is the largest eigenvalue of $\boldsymbol{\Sigma}$.

Vanilla Convex Formulations: Parallel Update via MM*

Majorized Problem for Spinu's Formulation

$$\underset{\boldsymbol{x}\geq\mathbf{0}}{\text{minimize}} \quad \frac{\lambda_{\max}}{2}\boldsymbol{x}^{\mathsf{T}}\boldsymbol{x} + \boldsymbol{x}^{\mathsf{T}}(\boldsymbol{\Sigma} - \lambda_{\max}\boldsymbol{I})\boldsymbol{x}^{k} - \boldsymbol{b}^{\mathsf{T}}\log(\boldsymbol{x}),$$

- Solving this majorized problem simplifies the optimization.

Solution to Majorized Problem

- Second order equation for x_i:

$$\lambda_{\max}x_i^2 + ((\boldsymbol{\Sigma} - \lambda_{\max}\boldsymbol{I})\boldsymbol{x}^{k})_i x_i - b_i = 0$$

- Positive solution:

$$x_i = \frac{-((\boldsymbol{\Sigma} - \lambda_{\max}\boldsymbol{I})\boldsymbol{x}^{k})_i + \sqrt{((\boldsymbol{\Sigma} - \lambda_{\max}\boldsymbol{I})\boldsymbol{x}^{k})_i^2 + 4\lambda_{\max}b_i}}{2\lambda_{\max}}.$$

Advantages of MM

- Allows for parallel updates by decoupling the elements of $\boldsymbol{x}$.
- Simplifies the optimization problem, making it more tractable.

Vanilla Convex Formulations: Parallel Update via SCA*

SCA Framework Overview (Scutari et al. 2014) (Palomar 2025, Appendix B)

- Solves optimization problems by iteratively solving simpler surrogate problems.
- Surrogate problems approximate the original objective function, making optimization more tractable.

Decoupling Elements with SCA

- The term $\boldsymbol{x}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x}$ couples all elements of $\boldsymbol{x}$, complicating parallel updates.
- SCA allows for decoupling by using a surrogate for $\boldsymbol{x}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x}$.

Surrogate for $\boldsymbol{x}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x}$

$$\frac{1}{2}\boldsymbol{x}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x} \approx \frac{1}{2}(\boldsymbol{x}^k)^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{x}^k + (\boldsymbol{\Sigma}\boldsymbol{x}^k)^\mathsf{T}(\boldsymbol{x}-\boldsymbol{x}^k) + \frac{1}{2}(\boldsymbol{x}-\boldsymbol{x}^k)^\mathsf{T}\mathrm{Diag}(\boldsymbol{\Sigma})(\boldsymbol{x}-\boldsymbol{x}^k)$$

where $\mathrm{Diag}(\boldsymbol{\Sigma})$ is a diagonal matrix with the diagonal of $\boldsymbol{\Sigma}$.

Vanilla Convex Formulations: Parallel Update via SCA*

Surrogate Problem for Spinu's Formulation

$$\underset{\boldsymbol{x}\geq\boldsymbol{0}}{\text{minimize}} \quad \frac{1}{2}\boldsymbol{x}^{\mathsf{T}}\text{Diag}(\boldsymbol{\Sigma})\boldsymbol{x} + \boldsymbol{x}^{\mathsf{T}}(\boldsymbol{\Sigma} - \text{Diag}(\boldsymbol{\Sigma}))\boldsymbol{x}^{k} - \boldsymbol{b}^{\mathsf{T}}\log(\boldsymbol{x}),$$

- Solving this surrogate problem simplifies the optimization.

Solution to Surrogate Problem

- Second order equation for x_i:

$$\Sigma_{ii}x_i^2 + ((\boldsymbol{\Sigma} - \text{Diag}(\boldsymbol{\Sigma}))\boldsymbol{x}^k)_i x_i - b_i = 0$$

- Positive solution:

$$x_i = \frac{-((\boldsymbol{\Sigma} - \text{Diag}(\boldsymbol{\Sigma}))\boldsymbol{x}^k)_i + \sqrt{((\boldsymbol{\Sigma} - \text{Diag}(\boldsymbol{\Sigma}))\boldsymbol{x}^k)_i^2 + 4\Sigma_{ii}b_i}}{2\Sigma_{ii}}.$$

Advantages of SCA

- Allows for parallel updates by decoupling the elements of $\boldsymbol{x}$.
- Simplifies the optimization problem, making it more tractable.

Outline

General Nonconvex Formulations

Risk Parity with Expected Return

- Enhanced risk parity considers expected return within the risk parity framework.
- Addresses criticism of risk parity's focus on risk over performance.

Vanilla Formulation

- Vanilla convex formulations focused on basic portfolio constraints.
- They enjoy convex reformulations optimal for risk budgeting equations:

$$w_i \left(\boldsymbol{\Sigma} \boldsymbol{w}\right)_i = b_i \boldsymbol{w}^{\mathsf{T}} \boldsymbol{\Sigma} \boldsymbol{w}, \quad i = 1, \ldots, N.$$

Realistic Scenarios with Additional Constraints

- Portfolio managers often have extra constraints (turnover, market-neutral, maximum-position, etc.).
- Additional objectives like maximizing expected return or minimizing variance/volatility.
- Convex formulations no longer applicable; nonconvex formulations required.

General Nonconvex Formulations

Approximate Satisfaction of Risk Budgeting Equations

$$w_i \left(\boldsymbol{\Sigma}\boldsymbol{w}\right)_i \approx b_i \boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}, \quad i = 1, \ldots, N.$$

Measures of Approximation Error

- Sum of squared relative risk-contribution errors:

$$\sum_{i=1}^{N}\left(\frac{w_i \left(\boldsymbol{\Sigma}\boldsymbol{w}\right)_i}{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}} - b_i\right)^2$$

- Sum of squared risk-contribution errors:

$$\sum_{i=1}^{N}\left(\frac{w_i \left(\boldsymbol{\Sigma}\boldsymbol{w}\right)_i}{\sqrt{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}}} - b_i\sqrt{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}}\right)^2$$

- Sum of squared volatility-scaled risk-contribution errors:

$$\sum_{i=1}^{N}\left(w_i \left(\boldsymbol{\Sigma}\boldsymbol{w}\right)_i - b_i \boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}\right)^2$$

General Nonconvex Formulations

Herfindahl Index for Risk Concentration

$$h(\boldsymbol{w}) = \sum_{i=1}^{N} \left(\frac{w_i \frac{\partial f}{\partial w_i}}{f(\boldsymbol{w})} \right)^2$$

Indicates risk diversification, with $1/N \leq h(\boldsymbol{w}) \leq 1$, where smaller index implies more diversified risk.

Alternative Norms for Error Measurement

- ℓ_1-norm, ℓ_∞-norm, Huber's robust penalty function, etc.
- Leads to various portfolio formulations with different convergence behaviors.

Application

- These measures and formulations are used to create portfolios that balance risk diversification with performance objectives, accommodating a range of constraints and preferences.

General Nonconvex Formulations

Maillard, Roncalli, and Teiletche's Formulation (Maillard, Roncalli, and Teiletche 2010)

$$\begin{array}{ll}\underset{\mathbf{w}}{\text{minimize}} & \sum_{i,j=1}^{N}\left(w_i\left(\boldsymbol{\Sigma}\mathbf{w}\right)_i - w_j\left(\boldsymbol{\Sigma}\mathbf{w}\right)_j\right)^2\\ \text{subject to} & \mathbf{w}\in\mathcal{W}\end{array}$$

Alternative Reformulation with Dummy Variable

$$\begin{array}{ll}\underset{\mathbf{w},\theta}{\text{minimize}} & \sum_{i=1}^{N}\left(w_i\left(\boldsymbol{\Sigma}\mathbf{w}\right)_i - \theta\right)^2\\ \text{subject to} & \mathbf{w}\in\mathcal{W}\end{array}$$

where the optimal θ is $\theta = \frac{1}{N}\mathbf{w}^{\mathsf{T}}\boldsymbol{\Sigma}\mathbf{w}$.

General Nonconvex Formulations

Bruder and Roncalli's Formulation (Bruder and Roncalli 2012)

$$\begin{array}{ll} \underset{\boldsymbol{w}}{\text{minimize}} & \sum_{i=1}^{N}\left(\frac{w_i\left(\boldsymbol{\Sigma}\boldsymbol{w}\right)_i}{\boldsymbol{w}^T\boldsymbol{\Sigma}\boldsymbol{w}}-b_i\right)^2 \\ \text{subject to} & \boldsymbol{w}\in\mathcal{W} \end{array}$$

Minimization of the Herfindahl Index

$$\begin{array}{ll} \underset{\boldsymbol{w}}{\text{minimize}} & \sum_{i=1}^{N}\left(\frac{w_i(\boldsymbol{\Sigma}\boldsymbol{w})_i}{\boldsymbol{w}^T\boldsymbol{\Sigma}\boldsymbol{w}}\right)^2 \\ \text{subject to} & \boldsymbol{w}\in\mathcal{W} \end{array}$$

which can be seen as particular case of Bruder and Roncalli's formulation with $b_i = 0$.

Numerical Issues and Recommendations

Maillard et al.'s Double-Summation Formulation

- Can suffer from numerical issues due to very small squared terms.
- Covariance matrix $\boldsymbol{\Sigma}$ may need artificial scaling.

Preferred Formulations for Numerical Stability

- Bruder and Roncalli's formulation.
- Minimization of the Herfindahl index.
- Based on normalized terms, offering better numerical stability.

Application

These formulations are used to create risk parity portfolios that also consider additional constraints and objectives, such as expected return, while maintaining numerical stability.

Unified Formulation

General Formulation (Feng and Palomar 2015)

$$\begin{array}{ll} \underset{\boldsymbol{w}}{\text{minimize}} & \sum_{i=1}^{N} g_i(\boldsymbol{w})^2 + \lambda F(\boldsymbol{w}) \\ \text{subject to} & \boldsymbol{w} \in \mathcal{W} \end{array}$$

Concentration Error Measure $g_i(\boldsymbol{w})$

- Represents the deviation of the ith asset's risk contribution from its target budget b_i.
- Example:

$$g_i(\boldsymbol{w}) = \frac{w_i\left(\boldsymbol{\Sigma}\boldsymbol{w}\right)_i}{\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}} - b_i.$$

Preference Function $F(\boldsymbol{w})$

- Encapsulates extra objectives, e.g., maximizing expected return or minimizing variance.
- Example:

$$F(\boldsymbol{w}) = -\boldsymbol{w}^\mathsf{T}\boldsymbol{\mu} + \frac{1}{2}\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w}$$

Unified Formulation

Trade-off Hyper-parameter λ

- Balances between minimizing concentration errors and optimizing the preference function.

Versatility of the Formulation

- Capable of incorporating various risk parity formulations and additional objectives.
- Adaptable to different error measures and preference functions.

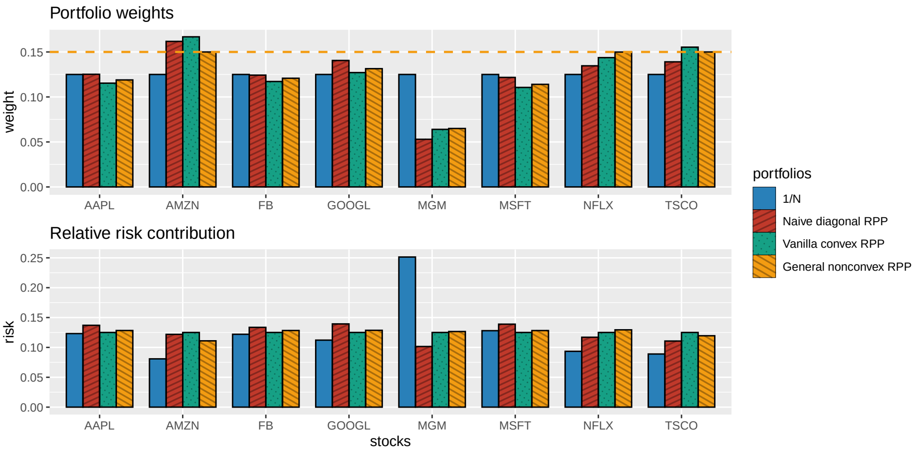
Challenges in Algorithm Design

- Nonconvexity of the term $\sum_{i=1}^{N} g_i(\boldsymbol{w})^2$ complicates the development of algorithms.
- Requires sophisticated optimization techniques to navigate the nonconvex landscape.

Significance

- This unified formulation offers a comprehensive framework for risk parity portfolio construction.
- It allows for the integration of risk management with performance optimization, accommodating a wide range of portfolio management preferences and constraints.

Portfolio allocation and risk contribution of general nonconvex RPP (with $w_i \leq 0.15$) compared to benchmarks ($1/N$ portfolio, naive diagonal RPP, and vanilla convex RPP):



General Nonconvex Formulations: Algorithms

Iterative Algorithms

- General-purpose solvers can address previous nonconvex formulations.
- Iterative algorithms can be developed for efficiency producing a sequence of iterates: $\boldsymbol{w}^0, \boldsymbol{w}^1, \boldsymbol{w}^2, \ldots$

Initial Point

- Initial point for algorithms can be the solution from vanilla convex formulation.
- Must ensure feasibility with all constraints in $\mathcal{W}$.
- Alternatively, use the $1/N$ portfolio as a simpler initial point.

Algorithms: SCA Primer

Original Difficult Problem

$$\begin{array}{ll} \underset{\boldsymbol{x}}{\text{minimize}} & f(\boldsymbol{x}) \\ \text{subject to} & \boldsymbol{x} \in \mathcal{X} \end{array}$$

where f is the (possibly nonconvex) objective function and $\mathcal{X}$ is the convex feasible set.

Successive Convex Approximation (SCA) Method (Scutari et al. 2014) (Palomar 2025, Appendix B)

- Approximates a difficult optimization problem by a sequence of simpler problems:

$$\boldsymbol{x}^{k+1} = \underset{\boldsymbol{x}\in\mathcal{X}}{\arg\min}\ \tilde{f}\left(\boldsymbol{x};\boldsymbol{x}^k\right), \qquad k = 0,1,2,\dots$$

  where $\tilde{f}(\boldsymbol{x};\boldsymbol{x}^k)$ approximates $f(\boldsymbol{x})$ around the current point $\boldsymbol{x}^k$.
- Produces a sequence of iterates $\boldsymbol{x}^0, \boldsymbol{x}^1, \boldsymbol{x}^2, \dots$ that converge to $\boldsymbol{x}^\star$.
- For convergence, we need a smoothing step to avoid oscillations ($\gamma^k \in (0,1]$):

$$\left.\begin{array}{l} \hat{\boldsymbol{x}}^{k+1} = \underset{\boldsymbol{x}\in\mathcal{X}}{\arg\min}\ \tilde{f}\left(\boldsymbol{x};\boldsymbol{x}^k\right) \\ \boldsymbol{x}^{k+1} = \boldsymbol{x}^k + \gamma^k\left(\hat{\boldsymbol{x}}^{k+1} - \boldsymbol{x}^k\right) \end{array}\right. \qquad k = 0,1,2,\dots$$

Application of SCA Method

- Unified formulation objective function:

$$U(\boldsymbol{w}) = \sum_{i=1}^{N} g_i(\boldsymbol{w})^2 + \lambda F(\boldsymbol{w})$$

- Convexification by linearizing $g_i(\boldsymbol{w})$ around $\boldsymbol{w}^k$:

$$g_i(\boldsymbol{w}) \approx g_i(\boldsymbol{w}^k) + \nabla g_i(\boldsymbol{w}^k)^\mathsf{T} \left(\boldsymbol{w} - \boldsymbol{w}^k\right)$$

- Surrogate function:

$$\tilde{U}(\boldsymbol{w}, \boldsymbol{w}^k) = \sum_{i=1}^{N} \left(g_i(\boldsymbol{w}^k) + \nabla g_i(\boldsymbol{w}^k)^\mathsf{T} \left(\boldsymbol{w} - \boldsymbol{w}^k\right)\right)^2 + \lambda F(\boldsymbol{w}) + \frac{\tau}{2} \left\|\boldsymbol{w} - \boldsymbol{w}^k\right\|_2^2$$

Approximated QP Formulation

$$\begin{array}{ll} \underset{\boldsymbol{w}}{\text{minimize}} & \frac{1}{2}\boldsymbol{w}^{\mathsf{T}}\boldsymbol{Q}^{k}\boldsymbol{w} + \boldsymbol{w}^{\mathsf{T}}\boldsymbol{q}^{k} + \lambda F(\boldsymbol{w}) \\ \text{subject to} & \boldsymbol{w} \in \mathcal{W}, \end{array}$$

where

$$\boldsymbol{Q}^{k} \triangleq 2\left(\boldsymbol{J}^{k}\right)^{\mathsf{T}}\boldsymbol{J}^{k} + \tau\boldsymbol{I},$$

$$\boldsymbol{q}^{k} \triangleq 2\left(\boldsymbol{J}^{k}\right)^{\mathsf{T}}\boldsymbol{g}^{k} - \boldsymbol{Q}^{k}\boldsymbol{w}^{k},$$

and

$$\boldsymbol{g}^{k} \triangleq \left[g_1(\boldsymbol{w}^{k}),\ldots,g_N(\boldsymbol{w}^{k})\right]^{\mathsf{T}}$$

$$\boldsymbol{J}^{k} \triangleq \begin{bmatrix} \nabla g_1(\boldsymbol{w}^{k})^{\mathsf{T}} \\ \vdots \\ \nabla g_N(\boldsymbol{w}^{k})^{\mathsf{T}} \end{bmatrix}.$$

Algorithms: SCA

Successive Convex optimization for RIsk Parity portfolio (SCRIP) (Feng and Palomar 2015)

Initialization:

- Start with an initial portfolio $\mathbf{w}^0$ within the feasible set $\mathcal{W}$.
- Define sequence $\{\gamma^k\}$.

Repeat (kth iteration):

1. Calculate risk concentration terms $\mathbf{g}^k$ and Jacobian matrix $\mathbf{J}^k$ for current point $\mathbf{w}^k$.
2. Solve approximated QP problem and keep solution as $\hat{\mathbf{w}}^{k+1}$.
3. Update the portfolio as $\mathbf{w}^{k+1} \leftarrow \mathbf{w}^k + \gamma^k(\hat{\mathbf{w}}^{k+1} - \mathbf{w}^k)$.
4. $k \leftarrow k + 1$.

Until: The solution converges to the optimal portfolio.

Algorithms: ALM

Alternate Linearization Method (ALM) Overview (Bai, Scheinberg, and Tütüncü 2016)

- Single-summation reformulation of Maillard's formulation.
- Objective function:

$$F(\boldsymbol{w}, \theta) = \sum_{i=1}^{N} \left(w_i \left(\boldsymbol{\Sigma} \boldsymbol{w}\right)_i - \theta\right)^2 = \sum_{i=1}^{N} \left(\boldsymbol{w}^\mathsf{T} \boldsymbol{M}_i \boldsymbol{w} - \theta\right)^2,$$

  where $\boldsymbol{M}_i$ contains the ith-row of $\boldsymbol{\Sigma}$ and zeros elsewhere.

ALM Strategy

- Introduce variable $\boldsymbol{y}$ and redefine objective as

$$F(\boldsymbol{w}, \boldsymbol{y}, \theta) = \sum_{i=1}^{N} \left(\boldsymbol{w}^\mathsf{T} \boldsymbol{M}_i \boldsymbol{y} - \theta\right)^2,$$

  subject to $\boldsymbol{y} = \boldsymbol{w}$.
- Then sequentially optimize $\boldsymbol{w}$, $\boldsymbol{y}$, and θ using two QP approximations.

QP Approximations in ALM

- First QP approximation:

$$Q^1(\boldsymbol{w}, \boldsymbol{y}^k, \theta) = F(\boldsymbol{w}, \boldsymbol{y}^k, \theta) + \nabla_2 F(\boldsymbol{y}^k, \boldsymbol{y}^k, \theta)^{\mathsf{T}}(\boldsymbol{w} - \boldsymbol{y}^k) + \frac{1}{2\mu}\|\boldsymbol{w} - \boldsymbol{y}^k\|_2^2$$

- Second QP approximation:

$$Q^2(\boldsymbol{w}^{k+1}, \boldsymbol{y}, \theta) = F(\boldsymbol{w}^{k+1}, \boldsymbol{y}, \theta) + \nabla_1 F(\boldsymbol{w}^{k+1}, \boldsymbol{w}^{k+1}, \theta)^{\mathsf{T}}(\boldsymbol{y} - \boldsymbol{w}^{k+1}) + \frac{1}{2\mu}\|\boldsymbol{y} - \boldsymbol{w}^{k+1}\|_2^2$$

Gradient Calculations for ALM

- Gradient with respect to $\boldsymbol{w}$:

$$\nabla_1 F(\boldsymbol{w}, \boldsymbol{y}, \theta) = 2\sum_{i=1}^{N}\left(\boldsymbol{w}^{\mathsf{T}}\boldsymbol{M}_i\boldsymbol{y} - \theta\right)\boldsymbol{M}_i\boldsymbol{y}$$

- Gradient with respect to $\boldsymbol{y}$:

$$\nabla_2 F(\boldsymbol{w}, \boldsymbol{y}, \theta) = 2\sum_{i=1}^{N}\left(\boldsymbol{w}^{\mathsf{T}}\boldsymbol{M}_i\boldsymbol{y} - \theta\right)\boldsymbol{M}_i^{\mathsf{T}}\boldsymbol{w}.$$

Numerical Issues

Nonconvex Formulation Challenges

- Initial nonconvex problem:

$$\begin{array}{ll} \underset{\mathbf{w},\theta}{\text{minimize}} & \sum_{i=1}^{N} \left(w_i \left(\mathbf{\Sigma w}\right)_i - \theta\right)^2 \\ \text{subject to} & \mathbf{w} \in \mathcal{W} \end{array}$$

- Squared terms $w_i \left(\mathbf{\Sigma w}\right)_i$ can be numerically unstable when small.

Numerical Stability Heuristic (Mausser and Romanko 2014)

- Scale up covariance matrix $\mathbf{\Sigma}$ by a large factor (e.g., 10^4) to mitigate numerical issues.

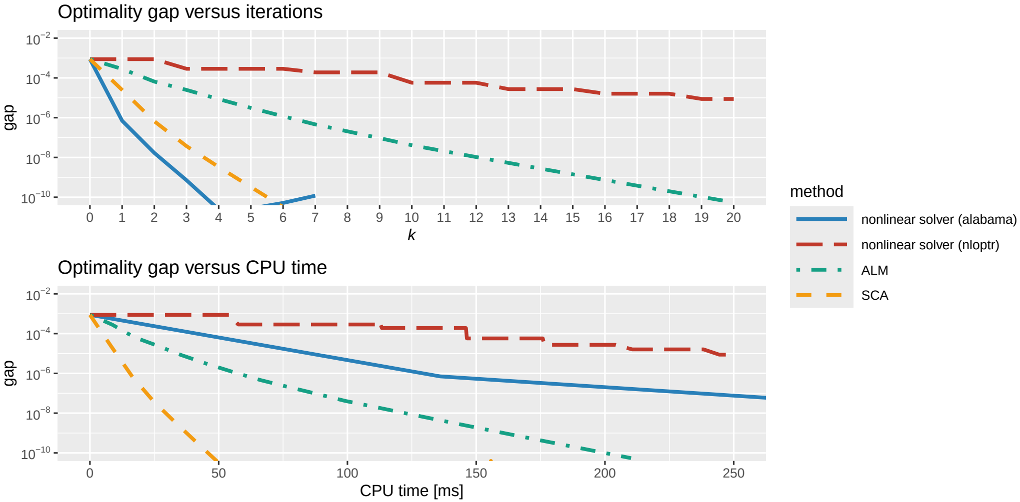
Preferred Formulation for Stability

- Use normalized terms for better numerical stability: $w_i \left(\mathbf{\Sigma w}\right)_i / (\mathbf{w}^\mathsf{T}\mathbf{\Sigma w})$

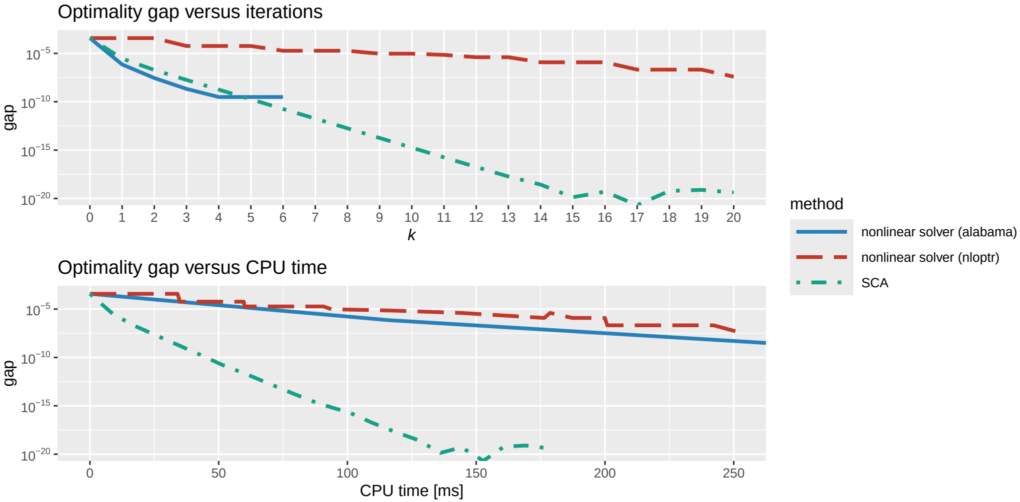
$$\begin{array}{ll} \underset{\mathbf{w}}{\text{minimize}} & \sum_{i=1}^{N} \left(\dfrac{w_i \left(\mathbf{\Sigma w}\right)_i}{\mathbf{w}^\mathsf{T}\mathbf{\Sigma w}} - b_i\right)^2 \\ \text{subject to} & \mathbf{w} \in \mathcal{W}. \end{array}$$

Numerical Experiments

Convergence of algorithms for nonconvex RPP formulation in terms of $w_i\left(\boldsymbol{\Sigma w}\right)_i$:



Convergence of algorithms for nonconvex RPP formulation in terms of $w_i\,(\boldsymbol{\Sigma}\boldsymbol{w})_i\,/(\boldsymbol{w}^\mathsf{T}\boldsymbol{\Sigma}\boldsymbol{w})$:



Outline

Summary

Diversification is key in portfolio design, as the saying goes, "don't put all your eggs in one basket." Some key points:

- The $1/N$ portfolio effectively diversifies capital allocation, but risk parity portfolios offer a more advanced strategy by diversifying risk allocation.
- Risk parity portfolios express the risk measure (e.g., volatility) as the sum of individual risk contributions from each asset, providing refined risk control compared to using a single overall portfolio risk value.
- Risk parity formulations have three levels of complexity:
  - **Naive diagonal formulation**: assumes a diagonal covariance matrix, simplifying to the inverse-volatility portfolio (ignoring asset correlations);
  - **Vanilla convex formulations**: consider simple long-only portfolios, rewritten in convex form with efficient algorithms; and
  - **General nonconvex formulations**: admit realistic constraints and extended objective functions, becoming nonconvex problems requiring careful resolution (still with efficient iterative algorithms).
